### REC\_Python\_Week 4\_CY

Attempt : 1  
Total Mark : 40  
Marks Obtained : 40

### Section 1 : Coding

#### 1. Problem Statement

Amrita is developing a password strength checker for her website. She wants the checker to consider the length and the diversity of characters used in the password. A strong password should be long and include a mix of character types: uppercase, lowercase, digits, and special symbols.

She also wants the feedback to be user-friendly, so she wants to include the actual password in the output. Help Amrita finish this password checker using Python's built-in string methods.

Character Types Considered:

Lowercase letters (a-z) Uppercase letters (A-Z) Digits (0-9) Special characters (from string.punctuation, e.g. @, !, #, \$)

### ***Input Format***

The input consists of a single string representing the user's password.

### ***Output Format***

The program prints the strength of the password in this format:

If the password length < 6 characters or fewer than 2 of the 4 character types, the output prints "<password> is Weak"

If password length  $\geq 6$  and at least 2 different character types, the output prints "<password> is Moderate"

If Password length  $\geq 10$  and all 4 character types present, the output prints "<password> is Strong"

Refer to the sample output for formatting specifications.

### ***Sample Test Case***

Input: password123

Output: password123 is Moderate

### ***Answer***

```
a=input()
b=len(a)
c=0
c1=0
c2=0
c3=0
c4=0
for i in a:
    if not i.isalnum():
        if c4<1:
            c+=1
            c4=1
    if i.islower():
        if c1<1:
            c+=1
            c1=1
```

```
if i.isdigit():
    if c2<1:
        c+=1
    c2=1
if i.isupper():
    if c3<1:
        c+=1
    c3=1
if b>=10 and c==4:
    print(a,"is Strong")
elif b>=6 and c>=2:
    print(a,"is Moderate")
elif b<6 or c<=2:
    print(a,"is Weak")
```

**Status :** Correct

**Marks :** 10/10

## 2. Problem Statement

Imagine you are tasked with developing a function for calculating the total cost of an item after applying a sales tax. The sales tax rate is equal to 0.08 and it is defined as a global variable.

The function should accept the cost of the item as a parameter, calculate the tax amount, and return the total cost.

Additionally, the program should display the item cost, sales tax rate, and total cost to the user.

Function Signature: `total_cost(item_cost)`

### ***Input Format***

The input consists of a single line containing a positive floating-point number representing the cost of the item.

### ***Output Format***

The output consists of three lines:

"Item Cost:" followed by the cost of the item formatted to two decimal places.

"Sales Tax Rate:" followed by the sales tax rate in percentage.

"Total Cost:" followed by the calculated total cost after applying the sales tax, formatted to two decimal places.

Refer to the sample output for formatting specifications.

### **Sample Test Case**

Input: 50.00

Output: Item Cost: \$50.00

Sales Tax Rate: 8.0%

Total Cost: \$54.00

### **Answer**

#

```
def total_cost(a):
```

```
    t=a*0.08
```

```
    t=t+a
```

```
    return t
```

```
SALES_TAX_RATE=0.08
```

```
item_cost=float(input())
```

```
total_cost = total_cost(item_cost)
```

```
print(f"Item Cost: ${item_cost:.2f}")
```

```
print(f"Sales Tax Rate: {SALES_TAX_RATE * 100}%")
```

```
print(f"Total Cost: ${total_cost:.2f}")
```

**Status : Correct**

**Marks : 10/10**

### **3. Problem Statement**

Develop a text analysis tool that needs to count the occurrences of a specific substring within a given text string.

Write a function `count_substrings(text, substring)` that takes two inputs: the text string and the substring to be counted. The function should count

how many times the substring appears in the text string and return the count.

Function Signature: count\_substrings(text, substring)

### ***Input Format***

The first line of the input consists of a string representing the text.

The second line consists of a string representing the substring.

### ***Output Format***

The output should display a single line of output containing the count of occurrences of the substring in the text string.

Refer to the sample output for the formatting specifications.

### ***Sample Test Case***

Input: programming is fun and programming is cool  
programming

Output: The substring 'programming' appears 2 times in the text.

### ***Answer***

```
a=list(input().split())
b=input()
count=0
for i in a:
    if b in i:
        count+=1
print(f"The substring '{b}' appears {count} times in the text.")
```

**Status :** Correct

**Marks :** 10/10

## **4. Problem Statement**

Meena is analyzing a list of integers and needs to count how many numbers in the list are even and how many are odd. She decides to use

lambda functions to filter the even and odd numbers from the list.

Write a program that takes a list of integers, counts the number of even and odd numbers using lambda functions, and prints the results.

### ***Input Format***

The first line contains an integer n, representing the number of integers in the list.

The second line contains n space-separated integers.

### ***Output Format***

The first line of output prints an integer representing the count of even numbers.

The second line of output prints an integer representing the count of odd numbers.

Refer to the sample output for the formatting specifications.

### ***Sample Test Case***

Input: 7

12 34 56 78 98 65 23

Output: 5

2

### ***Answer***

```
a=int(input())
b=list(input().split())
c=0
c1=0
c2=len(b)
even=lambda a : a%2==0
odd=lambda a : a%2!=0
for i in b:
    if(even(int(i))):
        c+=1
    if(odd(int(i))):
        c1+=1
```

```
print(c)  
print(c1)
```

**Status :** Correct

**Marks :** 10/10
